A: For Mathematical Engineering Engineering is the subject which relates the use of mathematics and sciences in Engineering, and more specifically, the practice and theory of engineering. Engineering begins with the study of natural phenomena and everyday objects, and may follow with more abstract matters like the laws of physics, construction of mathematical models of such things, and predictions of how those things work. Engineering involves the study of how to do all of this. The defining characteristic of an engineer is that he or she has the knowledge and skill to design and engineer various structures and machines, and that making such structures and machines is a major (or primary) part of the engineer's job. A physicist is one who studies matter. Physicists attempt to find general principles that operate in all of the kinds of physical world, from the electromagnetic forces of atoms to the huge, powerful forces that produce nuclear explosions. Some of the general principles are very well understood, like the fact that all physical particles, including atoms, have masses and forces of attraction, but more details of, for example, how and why electrons attract other electrons remain out of reach for physicists to understand completely. Many physicists work on the interface between the physical world and the laws of the mathematical universe. It is also interesting to note that some physicists have already forgotten or lost most of the mathematics that they knew in their early education and that many physicists are working in laboratories in which they do not need to know much mathematics. Note that the people who are doing engineering have a background in mathematics and physics. An engineering graduate would need to carry a set of textbooks called Professional Engineering Studies, which is not the same as mathematical engineering. It is not necessary to learn all about physics or about mathematics, but it is necessary to have a good grasp of mathematics, physics, and engineering. An advanced degree is required to

---

practice engineering in many countries. A mechanical engineer is one who designs, builds, and operates machinery. In the example of practical applications, one might build a bridge, or one might design the best car engine. A chemist is someone who studies the chemical structures and reactions of atoms and molecules. Chemists attempt to find out what sort of molecules or atoms are suitable for different purposes.
